我总算是找到Linux下好用的PDF编辑器啦

Lecture 2: Markov Decision Processes

David Silver

1 Markov Processes

2 Markov Reward Processes

- 3 Markov Decision Processes
- 4 Extensions to MDPs

Introduction

Introduction to MDPs

- \%-
- Markov decision processes formally describe an environment for reinforcement learning
- Where the environment is fully observable
- i.e. The current *state* completely characterises the process
- Almost all RL problems can be formalised as MDPs, e.g.
 - Optimal control primarily deals with continuous MDPs
 - Partially observable problems can be converted into MDPs
 - Bandits are MDPs with one state

Markov Property

Markov Property

"The future is independent of the past given the present"

Definition

A state S_t is Markov if and only if

$$\mathbb{P}[S_{t+1} \mid S_t] = \mathbb{P}[S_{t+1} \mid S_1, ..., S_t]$$

- The state captures all relevant information from the history
- Once the state is known, the history may be thrown away
- i.e. The state is a sufficient statistic of the future

State Transition Matrix

For a Markov state s and successor state s', the state transition probability is defined by

$$\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$$

State transition matrix \mathcal{P} defines transition probabilities from all states s to all successor states s',

状态转移矩阵里面的元素是概率, 所有元素之和是1

$$\mathcal{P} = from \begin{bmatrix} \mathcal{P}_{11} & \dots & \mathcal{P}_{1n} \\ \vdots & & & \\ \mathcal{P}_{n1} & \dots & \mathcal{P}_{nn} \end{bmatrix}$$

where each row of the matrix sums to 1.

Markov Process

A Markov process is a memoryless random process, i.e. a sequence of random states $S_1, S_2, ...$ with the Markov property.

Definition

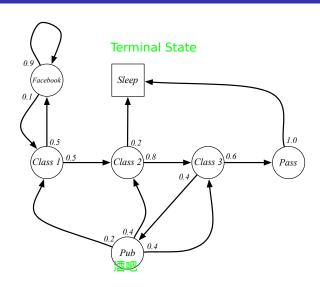

A Markov Process (or Markov Chain) is a tuple $\langle S, P \rangle$

- lacksquare $\mathcal S$ is a (finite) set of states
- \mathcal{P} is a state transition probability matrix, $\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$

马尔科夫链==马尔科夫过程,包含两个东西:

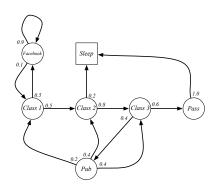

1. 状态集 2. 状态转移矩阵

Example: Student Markov Chain

Example: Student Markov Chain Episodes

玩一把游戏就是一个episodes

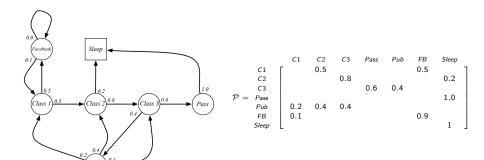

Sample episodes for Student Markov Chain starting from $S_1 = C1$

$$S_1, S_2, ..., S_T$$

- C1 C2 C3 Pass Sleep

- C1 C2 C3 Pub C2 C3 Pass Sleep
- C1 FB FB C1 C2 C3 Pub C1 FB FB FB C1 C2 C3 Pub C2 Sleep

Example: Student Markov Chain Transition Matrix

∟_{MRP}

Markov Reward Process

A Markov reward process is a Markov chain with values.

Definition

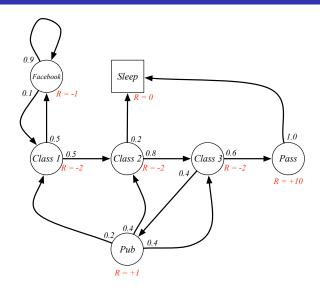

A Markov Reward Process is a tuple $\langle \mathcal{S}, \mathcal{P}, \mathcal{R}, \gamma \rangle$

- lacksquare \mathcal{S} is a finite set of states
- $lackbox{}{\mathcal{P}}$ is a state transition probability matrix,

$$\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$$
 immediate reward

- \mathcal{R} is a reward function, $\mathcal{R}_s = \mathbb{E}\left[R_{t+1} \mid S_t = s\right]$ 仅仅在s这个状态下,下一刻
- γ is a discount factor, $\gamma \in [0,1]$ 我得到的reward是多少

Example: Student MRP

Return

Return

Definition

The return G_t is the total discounted reward from time-step t.

$$G_t = R_{t+1} + \gamma R_{t+2} + \dots = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1}$$

- The discount $\gamma \in [0,1]$ is the present value of future rewards
- The value of receiving reward R after k+1 time-steps is $\gamma^k R$.
- This values immediate reward above delayed reward.
 - lacksquare γ close to 0 leads to "myopic" evaluation
 - $lue{\gamma}$ close to 1 leads to "far-sighted" evaluation

Why discount?

Most Markov reward and decision processes are discounted. Why?

- Mathematically convenient to discount rewards
- Avoids infinite returns in cyclic Markov processes
- Uncertainty about the future may not be fully represented
- If the reward is financial, immediate rewards may earn more interest than delayed rewards
- Animal/human behaviour shows preference for immediate reward
- It is sometimes possible to use *undiscounted* Markov reward processes (i.e. $\gamma=1$), e.g. if all sequences terminate.

Value Function

The value function v(s) gives the long-term value of state s

Definition

The state value function v(s) of an MRP is the expected return starting from state s

$$v(s) = \mathbb{E}\left[G_t \mid S_t = s\right]$$

Example: Student MRP Returns

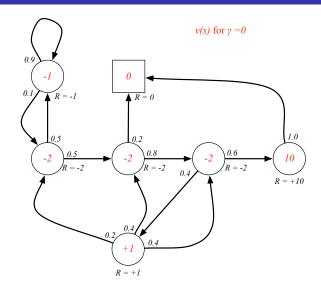

Sample returns for Student MRP: Starting from $S_1 = C1$ with $\gamma = \frac{1}{2}$

$$G_1 = R_2 + \gamma R_3 + \dots + \gamma^{T-2} R_T$$

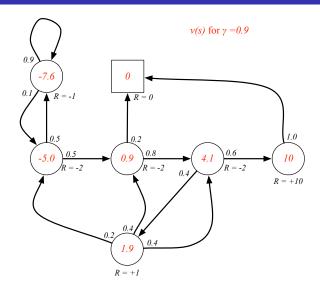

C1 C2 C3 Pass Sleep
$$v_1 = -2 - 2 * \frac{1}{2} - 2 * \frac{1}{4} + 10 * \frac{1}{8} \\ v_1 = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_1 = -2 - 1 * \frac{1}{2} - 2 * \frac{1}{4} + 1 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_2 = -2 - 2 * \frac{1}{2} - 2 * \frac{1}{4} + 1 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_3 = -3.125 \\ v_1 = -2 - 2 * \frac{1}{2} - 2 * \frac{1}{4} + 1 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_1 = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_1 = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_1 = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_1 = -3.20 \\ v_2 = -3.20 \\ v_3 = -3.20 \\ v_4 = -3.20 \\ v_5 = -3.20 \\ v_6 = -3.25 \\ v_7 = -3.20 \\ v_8 = -3.25 \\ v_9 = -3$$

└─Value Function

Example: State-Value Function for Student MRP (1)

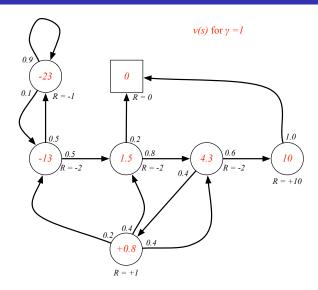

Example: State-Value Function for Student MRP (2)

└─Value Function

Example: State-Value Function for Student MRP (3)

Bellman Equation for MRPs

The value function can be decomposed into two parts:

- \blacksquare immediate reward R_{t+1}
- discounted value of successor state $\gamma v(S_{t+1})$

$$v(s) = \mathbb{E} [G_t \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots \mid S_t = s]$$

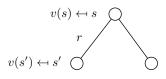

$$= \mathbb{E} [R_{t+1} + \gamma (R_{t+2} + \gamma R_{t+3} + \dots) \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma G_{t+1} \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma v(S_{t+1}) \mid S_t = s]$$

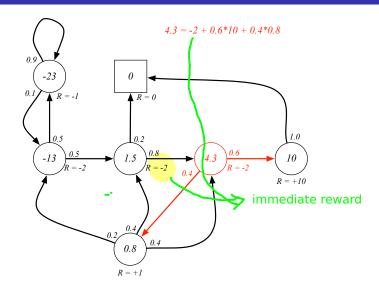

Bellman Equation for MRPs (2)

$$v(s) = \mathbb{E}\left[R_{t+1} + \gamma v(S_{t+1}) \mid S_t = s\right]$$

$$v(s) = \mathcal{R}_s + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'} v(s')$$

Example: Bellman Equation for Student MRP

Bellman Equation in Matrix Form

The Bellman equation can be expressed concisely using matrices,

$$\mathbf{v} = \mathcal{R} + \gamma \mathcal{P} \mathbf{v}$$

where v is a column vector with one entry per state

$$\begin{bmatrix} v(1) \\ \vdots \\ v(n) \end{bmatrix} = \begin{bmatrix} \mathcal{R}_1 \\ \vdots \\ \mathcal{R}_n \end{bmatrix} + \gamma \begin{bmatrix} \mathcal{P}_{11} & \dots & \mathcal{P}_{1n} \\ \vdots & & \\ \mathcal{P}_{11} & \dots & \mathcal{P}_{nn} \end{bmatrix} \begin{bmatrix} v(1) \\ \vdots \\ v(n) \end{bmatrix}$$

Transition Matrix

Solving the Bellman Equation

- The Bellman equation is a linear equation
- It can be solved directly:

$$egin{aligned} \mathbf{v} &= \mathcal{R} + \gamma \mathcal{P} \mathbf{v} \\ egin{aligned} \left(\mathbf{I} - \gamma \mathcal{P}
ight) \mathbf{v} &= \mathcal{R} \\ \mathbf{v} &= \left(\mathbf{I} - \gamma \mathcal{P}
ight)^{-1} \mathcal{R} \\ &\qquad \qquad \mathbf{t}$$
 计算复杂度是怎么算的?

- Computational complexity is $O(n^3)$ for n states
- Direct solution only possible for small MRPs
- There are many iterative methods for large MRPs, e.g.
 - Dynamic programmingMonte-Carlo evaluation
- 这就是为什么要学这些。
- Temporal-Difference learning

Markov Decision Process

A Markov decision process (MDP) is a Markov reward process with decisions. It is an *environment* in which all states are Markov.

Definition

A Markov Decision Process is a tuple $\langle S, A, P, R, \gamma \rangle$

- lacksquare $\mathcal S$ is a finite set of states
- A is a finite set of actions 多了一个Action,作为输入
- \mathcal{P} is a state transition probability matrix,
 - $\mathcal{P}_{ss'}^{\mathbf{a}} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s, A_t = \mathbf{a}\right]$
- lacksquare \mathcal{R} is a reward function, $\mathcal{R}_s^{\mathsf{a}} = \mathbb{E}\left[R_{t+1} \mid S_t = s, A_t = \mathsf{a}\right]$
- γ is a discount factor $\gamma \in [0, 1]$.

Example: Student MDP

Facebook R = -1因为是决策, 这里箭头上就 没有概率可言 Quit R = 0Facebook $Sleep \\
R = 0$ R = -1Study Study Study R = +10R = -2R = -2

去酒吧后的行为是随机的,因此有概率在箭头上

Policies (1)

Definition

A *policy* π is a distribution over actions given states,

$$\pi(a|s) = \mathbb{P}\left[A_t = a \mid S_t = s\right]$$

- A policy fully defines the behaviour of an agent
- MDP policies depend on the current state (not the history)
- i.e. Policies are *stationary* (time-independent), $A_t \sim \pi(\cdot|S_t), \forall t > 0$

和时间无关,只和状态有关

Policies (2)

└ Policies

- Given an MDP $\mathcal{M} = \langle \mathcal{S}, \mathcal{A}, \mathcal{P}, \mathcal{R}, \gamma \rangle$ and a policy π
- The state sequence $S_1, S_2, ...$ is a Markov process $\langle \mathcal{S}, \mathcal{P}^{\pi} \rangle$
- The state and reward sequence $S_1, R_2, S_2, ...$ is a Markov reward process $\langle \mathcal{S}, \mathcal{P}^{\pi}, \mathcal{R}^{\pi}, \gamma \rangle$
- where

$$\mathcal{P}^{\pi}_{s,s'} = \sum_{a \in \mathcal{A}} \pi(a|s) \mathcal{P}^{a}_{ss'}$$
 $\mathcal{R}^{\pi}_{s} = \sum_{a \in \mathcal{A}} \pi(a|s) \mathcal{R}^{a}_{s}$

└─Value Functions

Value Function

Definition

The state-value function $v_{\pi}(s)$ of an MDP is the expected return starting from state s, and then following policy π

$$v_{\pi}(s) = \mathbb{E}_{\pi}\left[G_t \mid S_t = s\right]$$

说的是用pi策略,在s这种状态下有多好

Definition

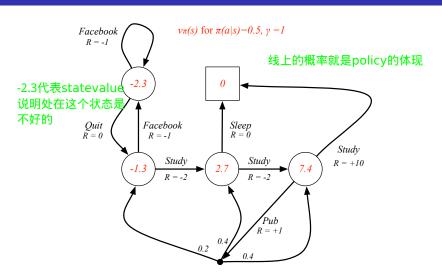

The action-value function $q_{\pi}(s,a)$ is the expected return starting from state s, taking action a, and then following policy π

$$q_{\pi}(s,a) = \mathbb{E}_{\pi}\left[G_t \mid S_t = s, A_t = a\right]$$

说得是用pi策略,在s状态下采取行动a有多好

└─Value Functions

Example: State-Value Function for Student MDP

Bellman Expectation Equation

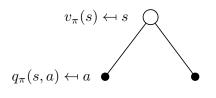

The state-value function can again be decomposed into immediate reward plus discounted value of successor state,

$$v_{\pi}(s) = \mathbb{E}_{\pi} \left[R_{t+1} + \gamma v_{\pi}(S_{t+1}) \mid S_t = s \right]$$

The action-value function can similarly be decomposed,

$$q_{\pi}(s, a) = \mathbb{E}_{\pi} \left[R_{t+1} + \gamma q_{\pi}(S_{t+1}, A_{t+1}) \mid S_t = s, A_t = a \right]$$

Bellman Expectation Equation for V^π

期望 概率*値
$$v_{\pi}(s) = \sum_{a \in \mathcal{A}} \pi(a|s)q_{\pi}(s,a)$$

Bellman Expectation Equation

Bellman Expectation Equation for Q^{π}

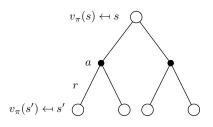

关注 action用黑色 关注state用白色

$$q_{\pi}(s,a) \longleftrightarrow s,a$$
 r
 $v_{\pi}(s') \longleftrightarrow s'$

$$q_{\pi}(s, a) = \mathcal{R}_{s}^{a} + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^{a} v_{\pi}(s')$$

Bellman Expectation Equation

Bellman Expectation Equation for v_{π} (2)

$$v_{\pi}(s) = \sum_{a \in \mathcal{A}} \pi(a|s) \left(\mathcal{R}_{s}^{a} + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^{a} v_{\pi}(s')\right)$$

Bellman Expectation Equation for q_{π} (2)

$$q_{\pi}(s,a) \longleftrightarrow s,a$$

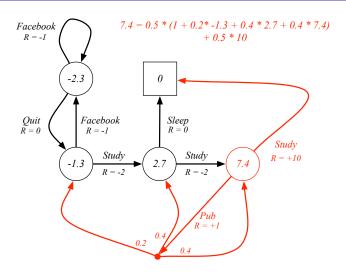

$$r$$

$$s'$$

$$q_{\pi}(s',a') \longleftrightarrow a'$$

$$q_{\pi}(s, a) = \mathcal{R}_{s}^{a} + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^{a} \sum_{a' \in \mathcal{A}} \pi(a'|s') q_{\pi}(s', a')$$

Example: Bellman Expectation Equation in Student MDP

Bellman Expectation Equation (Matrix Form)

The Bellman expectation equation can be expressed concisely using the induced MRP,

$$\mathbf{v}_{\pi} = \mathcal{R}^{\pi} + \gamma \mathcal{P}^{\pi} \mathbf{v}_{\pi}$$

with direct solution

$$v_{\pi} = (I - \gamma \mathcal{P}^{\pi})^{-1} \mathcal{R}^{\pi}$$

Optimal Value Function

Definition

The *optimal state-value function* $v_*(s)$ is the maximum value function over all policies

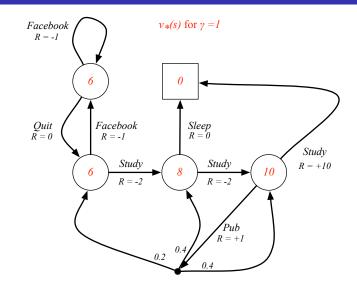

$$v_*(s) = \max_{\pi} v_{\pi}(s)$$

The optimal action-value function $q_*(s,a)$ is the maximum action-value function over all policies

$$q_*(s,a) = \max_{\pi} q_{\pi}(s,a)$$
 这个是最终的目的

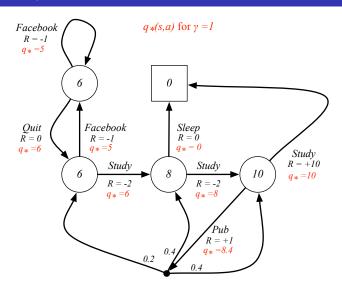

- The optimal value function specifies the best possible performance in the MDP.
- An MDP is "solved" when we know the optimal value fn.

Example: Optimal Value Function for Student MDP

Optimal Value Functions

Example: Optimal Action-Value Function for Student MDP

Optimal Policy

Define a partial ordering over policies

$$\pi \geq \pi'$$
 if $v_{\pi}(s) \geq v_{\pi'}(s), \forall s$

$\mathsf{Theorem}$

For any Markov Decision Process

- There exists an optimal policy π_* that is better than or equal to all other policies, $\pi_* \geq \pi, \forall \pi$
- All optimal policies achieve the optimal value function, $v_{\pi_*}(s) = v_*(s)$
- All optimal policies achieve the optimal action-value function, $q_{\pi_*}(s,a) = q_*(s,a)$

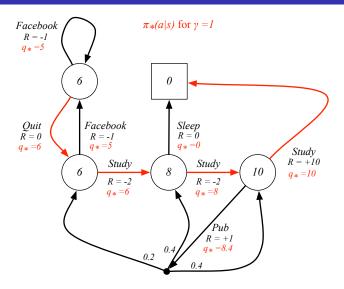

Finding an Optimal Policy

An optimal policy can be found by maximising over $q_*(s, a)$,

$$\pi_*(a|s) = \left\{ egin{array}{ll} 1 & ext{if } a = ext{argmax } q_*(s,a) \ & a \in \mathcal{A} \ 0 & otherwise \end{array}
ight.$$

- There is always a deterministic optimal policy for any MDP
- If we know $q_*(s, a)$, we immediately have the optimal policy

Example: Optimal Policy for Student MDP

Bellman Optimality Equation for v_*

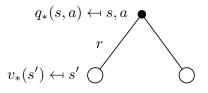

The optimal value functions are recursively related by the Bellman optimality equations:

$$v_*(s) \longleftrightarrow s$$

$$q_*(s,a) \longleftrightarrow a$$

$$v_*(s) = \max_a q_*(s,a)$$

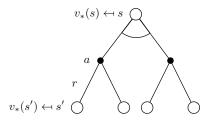

Bellman Optimality Equation for Q^*

$$q_*(s, a) = \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a v_*(s')$$

Bellman Optimality Equation

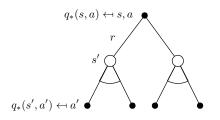

Bellman Optimality Equation for V^* (2)

$$v_*(s) = \max_{a} \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a v_*(s')$$

Bellman Optimality Equation

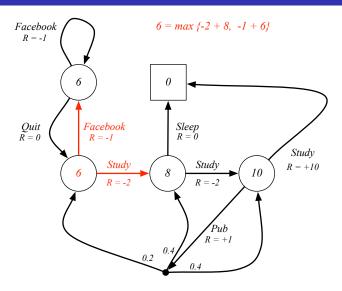

Bellman Optimality Equation for Q^* (2)

$$q_*(s, a) = \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a \max_{a'} \, q_*(s', a')$$

Bellman Optimality Equation

Example: Bellman Optimality Equation in Student MDP

Solving the Bellman Optimality Equation

- Bellman Optimality Equation is non-linear
- No closed form solution (in general)
- Many iterative solution methods
 - Value Iteration
 - Policy Iteration
 - Q-learning
 - Sarsa

Extensions to MDPs

(no exam)

- Infinite and continuous MDPs
- Partially observable MDPs
- Undiscounted, average reward MDPs

└ Infinite MDPs

The following extensions are all possible:

- Countably infinite state and/or action spaces
 - Straightforward
- Continuous state and/or action spaces
 - Closed form for linear quadratic model (LQR)
- Continuous time
 - Requires partial differential equations
 - Hamilton-Jacobi-Bellman (HJB) equation
 - $lue{}$ Limiting case of Bellman equation as time-step ightarrow 0

A Partially Observable Markov Decision Process is an MDP with hidden states. It is a hidden Markov model with actions.

Definition

A *POMDP* is a tuple $\langle \mathcal{S}, \mathcal{A}, \mathcal{O}, \mathcal{P}, \mathcal{R}, \mathcal{Z}, \gamma \rangle$

- lacksquare $\mathcal S$ is a finite set of states
- lacksquare \mathcal{A} is a finite set of actions
- O is a finite set of observations
- \mathcal{P} is a state transition probability matrix,

$$\mathcal{P}_{ss'}^{a} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s, A_t = a\right]$$

- lacksquare \mathcal{R} is a reward function, $\mathcal{R}_s^a = \mathbb{E}\left[R_{t+1} \mid S_t = s, A_t = a\right]$
- **2** is an observation function, $\mathcal{Z}_{s'o}^a = \mathbb{P}\left[O_{t+1} = o \mid S_{t+1} = s', A_t = a\right]$
- \bullet γ is a discount factor $\gamma \in [0, 1]$.

Belief States

(no exam)

Definition

A *history* H_t is a sequence of actions, observations and rewards,

$$H_t = A_0, O_1, R_1, ..., A_{t-1}, O_t, R_t$$

Definition

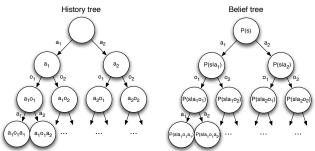

A belief state b(h) is a probability distribution over states, conditioned on the history h

$$b(h) = (\mathbb{P}[S_t = s^1 \mid H_t = h], ..., \mathbb{P}[S_t = s^n \mid H_t = h])$$

Reductions of POMDPs

(no exam)

- The history H_t satisfies the Markov property
- The belief state $b(H_t)$ satisfies the Markov property

- A POMDP can be reduced to an (infinite) history tree
- A POMDP can be reduced to an (infinite) belief state tree

Ergodic Markov Process

(no exam)

An ergodic Markov process is

- Recurrent: each state is visited an infinite number of times
- Aperiodic: each state is visited without any systematic period

Theorem

An ergodic Markov process has a limiting stationary distribution $d^{\pi}(s)$ with the property

$$d^{\pi}(s) = \sum_{s' \in \mathcal{S}} d^{\pi}(s') \mathcal{P}_{s's}$$

Ergodic MDP

(no exam)

Definition

An MDP is ergodic if the Markov chain induced by any policy is ergodic.

For any policy π , an ergodic MDP has an average reward per time-step ρ^{π} that is independent of start state.

$$ho^{\pi} = \lim_{T o \infty} rac{1}{T} \mathbb{E} \left[\sum_{t=1}^{T} R_t
ight]$$

Average Reward Value Function

(no exam)

- The value function of an undiscounted, ergodic MDP can be expressed in terms of average reward.
- $\tilde{v}_{\pi}(s)$ is the extra reward due to starting from state s,

$$ilde{v}_{\pi}(s) = \mathbb{E}_{\pi} \left[\sum_{k=1}^{\infty} \left(\mathsf{R}_{t+k} -
ho^{\pi}
ight) \mid \mathsf{S}_{t} = s
ight]$$

There is a corresponding average reward Bellman equation,

$$egin{aligned} ilde{v}_{\pi}(s) &= \mathbb{E}_{\pi} \left[(R_{t+1} -
ho^{\pi}) + \sum_{k=1}^{\infty} (R_{t+k+1} -
ho^{\pi}) \mid S_{t} = s
ight] \ &= \mathbb{E}_{\pi} \left[(R_{t+1} -
ho^{\pi}) + ilde{v}_{\pi}(S_{t+1}) \mid S_{t} = s
ight] \end{aligned}$$
